#### Abstract

The structure of the cationic polymerization initiator 9-anthrylmethyl cation is studied. By means of quantum-chemical calculations the bands in the UV region characteristic of this cation are assigned. It is shown that the changes in its electronic spectrum are caused by structural changes.

9-Anthrylmethyl hexafluorophosphate prepared by the interaction shown in Scheme 1 is a stable primary carbenium salt which initiates the polymerization of vinyl and heterocyclic monomers with low

Scheme 1
reactivity such as styrene, isobutene, 1,2-dimethoxyethylene, and 4 -methyl-1-pentene [1, 2]. This initiator has higher reactivity than trityl and diphenylmethyl salts. Its spectral characteristics, initiation ability and initiation mechanism of polymerization of $\alpha$-methylstyrene and $p$-methoxystyrene were studied in previous papers $[2,3]$. The high reactivity of the cation may be followed by changes in the electronic spectra of the initiator solutions. The interest in this initiator is also arisen by its photoreactivity. On irradiation with the light at $\lambda=366 \mathrm{~nm}$ it forms dimers [4]. This reaction was used for intra- and intermolecular cyclization of oligomers [5, 6].
The aim of this work is to study further the structure of 9 -anthrylmethyl cation and the reasons for the changes in its electronic spectrum.

## EXPERIMENTAL

9-Chloromethylanthracene (Fluka) was recrystallized and dried in vacuo. Silver hexafluorophosphate (Fluka) was dried in vacuo. Methylene dichloride was distilled and dried over $\mathrm{CaH}_{2}$ and $\mathrm{LiAlH}_{4}$ on a vacuum line.
The preparation of 9 -anthrylmethyl hexafluorophosphate was carried out by mixing of methylene dichloride solutions of 9-chloromethylanthracene and $\mathrm{AgPF}_{6}$ in vacuo $\left(6.67 \times 10^{-4} \mathrm{~Pa}\right)$ at room tempera-
ture. The reaction mixture became immediately bright orange in colour. The precipitate of AgCl was removed.
Although the MNDO method [7, 8] was parametrized to reproduce ground-state properties of neutral molecules, it also gives good results for positive and negative ions [9]. An exception are the ions where the charge is concentrated on one atom [10].

The full geometry optimizations of all the studied compounds were carried out by means of the MNDO method [7] using Davidon-Fletcher-Powell procedure with MNDOC program package [11]. The CNDO/S-CI method [12, 13] was used to predict the UV spectrum of the anthrylmethyl cation $\mathrm{ACH}_{2}^{+}$.

## RESULTS AND DISCUSSION

9-Anthrylmethyl cation $\left(\mathrm{ACH}_{2}^{+}\right)$is formed from 9chloromethylanthracene $\left(\mathrm{ACH}_{2} \mathrm{Cl}\right)$ after abstraction of chloride ion $\mathrm{Cl}^{-}$. The stability of this primary carbenium ion is due to the delocalization of the positive charge on the anthryl fragment. In addition, it forms an ion pair with the stable counter ion, $\mathrm{PF}_{6}^{-}$ [2]. We assumed that the process

$$
\mathrm{ACH}_{2} \mathrm{Cl} \rightarrow \mathrm{ACH}_{2}^{+}+\mathrm{Cl}^{-}
$$

is nonadiabatic, i.e. it is so fast that the geometry of the anthrylmethylene skeleton $\mathrm{ACH}_{2}$ does not change after abstraction of $\mathrm{Cl}^{-}$from $\mathrm{ACH}_{2} \mathrm{Cl}$. Therefore after the MNDO geometry optimization of $\mathrm{ACH}_{2} \mathrm{Cl}$, a single SCF calculation for $\mathrm{ACH}_{2}^{+}$at the same geometry of anthrylmethylene skeleton was carried out. The energetic effect of the process is calculated to be $573.2 \mathrm{~kJ} \mathrm{~mol}^{-1}$. The difference in the heats of formation for $\mathrm{ACH}_{2}^{+}$cation after the abstraction of $\mathrm{Cl}^{-}$from $\mathrm{ACH}_{2} \mathrm{Cl}$ and $\mathrm{ACH}_{2}^{+}$in equilibrium state $\left(\mathrm{ACH}_{2}^{+}(\mathrm{eq})\right)$ which is $139.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$ represents the energy of reorganization (in vapour phase) for $\mathrm{ACH}_{2}^{+}$at the transition from nonadiabatic to equilibrium state.

Table 1. Heats of Formation ( $\mathrm{kJ} \mathrm{mol}^{-1}$ ) and Charge of the Aliphatic Carbon Atom of the Compounds Studied

| Compound | $H_{\mathrm{f}}(\mathrm{MNDO})$ | kJ mol |
| :---: | :---: | :---: |
|  | 209.2 |  |
| $\mathrm{ACH}_{2} \mathrm{Cl} / \mathrm{el}$ |  |  |
| $\mathrm{ACH}_{2}^{+}$ | 1151.0 | 0.209 |
| $\mathrm{ACH}_{2}^{+}(\mathrm{eq})^{a}$ | 101.7 | 0.140 |
| $\mathrm{Cl}^{\boldsymbol{a}}$ | -229.8 |  |

a) $H_{t}($ AM1 $)=1025.1 \mathrm{~kJ} \mathrm{~mol}^{-1}[14] ;$ b) $H_{\mathrm{t}}$ (exp.) $=-233.9 \mathrm{~kJ}$ $\mathrm{mol}^{-1}$ [10].

The control experiments proved that even the "aged" initiator $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ preserves its initiation ability. The higher reactivity of the cation obtained in situ correlates with the more positive net charge of the aliphatic carbon atom of $\mathrm{ACH}_{2}^{+}$in comparison with $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ (Table 1).
The structural changes occurring as a result of the abstraction of $\mathrm{Cl}^{-}$from $\mathrm{ACH}_{2} \mathrm{Cl}$ and the formation of the cation $\mathrm{ACH}_{2}^{+}$are mainly expressed in an intensive shortening of the exocyclic carbon bond by $0.137 \AA$ and prolongation of its neighbouring

MNDO calculated structures of the anthrylmethyl cation.
carbon bonds (see formulas). The methylene group is situated in the plane of the anthryl fragment. Slight deviations from the planar geometry were found for the anthrylmethyl cation. This result is in agreement with the AM1 calculations by Ford and Hermann [14]. According to these authors, this is a nonplanar structure with a vertical symmetry plane.
The electronic spectrum of 9 -anthrylmethyl hexafluorophosphate in methylene dichloride at room temperature is shown in Fig. 1. Calculations with

Fig. 1. Electronic spectrum of 9 -anthrylmethyl hexafluorophosphate in methylene dichloride at room temperature. The CNDO/S-CI computed transitions are marked by lines: solid line - $\mathrm{ACH}_{2}^{+}$, dashed line $-\mathrm{ACH}_{2}^{+}(\mathrm{eq})$.

CNDO/S method were carried out for interpretation of the electronic spectrum of $\mathrm{ACH}_{2}^{+}$. These calculations show that the bands at $\lambda=476.8 \mathrm{~nm}$ and 373 nm might be caused by electron transitions in nonadiabatic structure of $\mathrm{ACH}_{2}^{+}$cation, while the bands at $\lambda=401.1,392.9$, and 354 nm are probably associated with electron transitions in $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ (Fig. 1).
The bands at $\lambda=392.9,373$, and 354 nm are characteristic of all compounds containing anthrylmethyl ( $\mathrm{ACH}_{2}$-) group (e.g. the spectra of $\mathrm{ACH}_{3}$ and $\mathrm{ACH}_{2} \mathrm{Cl}$ ). Probably the initiator exists in two forms, $\mathrm{ACH}_{2}^{+}$and $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$, and its spectrum is superposition of the bands of these two cation forms. The band at $\lambda=593.4 \mathrm{~nm}$ is not interpreted because it is not characteristic of anthracene derivatives and of the cationic forms as it remains unchanged after the reaction vessel is opened and the cation is desactivated [2]. Probably this band is due to side condensation products or complexes [3].
The influence of the configuration interaction (CI) on the calculated energy of the electron transitions $(\lambda)$, the values of the oscillator strengths $f$, and the percentual share (> $7 \%$ ) of the monoexcited configurations $V i$ ( $i$ - occupied MO, $j$ - unoccupied MO) in the Cl calculated spectral bands are shown in Table 2. For $\mathrm{Cl}=240,16$ occupied MO's and 15 unoccupied MO's were included in Cl . For $\mathrm{Cl}=525$

Table 2. Influence of the Configuration Interaction $(\mathrm{Cl})$ on the $\mathrm{CNDO} / \mathrm{S}-\mathrm{Cl}$ Calculated Electron Transitions of $\mathrm{ACH}_{2}^{+}$

| Compound | $\mathrm{Cl}=240$ |  |  | $\mathrm{Cl}=525$ |  |  | $\mathrm{Cl}=980$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\lambda / \mathrm{nm}$ | $f$ | V//\% | $\lambda / \mathrm{nm}$ | $f$ | V/I\% | $\lambda / \mathrm{nm}$ | $f$ | V/I\% |
| $\mathrm{ACH}_{2}^{+}$ | 459.8 | 0.105 | $84\left(V_{2}^{1}\right), 8\left(V_{3}^{1}\right)$ | 463.7 | 0.105 | $84\left(V_{2}^{1}{ }^{\prime}\right), 8\left(V_{3}^{1{ }^{\prime}}\right)$ | 472.9 | 0.292 | $64\left(V_{1}^{1}{ }^{+}\right), 23\left(V_{2}^{1}{ }^{+}\right)$ |
|  | 440.4 | 0.363 | $90\left(V_{1}^{1}\right)$ | 447.5 | 0.364 | $90\left(V_{1}^{+}\right)$ | 472.0 | 0.180 | $61\left(V_{2}^{+}\right), 25\left(V_{1}^{+}\right)$ |
|  | 361.6 | 0.297 | $79\left(V_{3}^{1}\right), 8\left(V_{2}^{1}\right)$ | 363.6 | 0.305 | $\left.79\left(V_{3}^{1}\right)^{\circ}\right), 8\left(V_{2}^{1}\right)$ | 367.9 | 0.319 | $80\left(V_{3}^{+}\right), 8\left(V_{2}^{+}\right)$ |
| $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ | 398.7 | 0.268 | $79\left(V_{2}^{1}\right), 9\left(V_{3}^{1}\right)$ | 402.9 | 0.267 | $79\left(V_{2}^{1}\right), 8\left(V_{3}^{+}\right)$ | 412.3 | 0.276 | $81\left(V_{2}^{1}\right), 7\left(V_{3}^{1}\right)$ |
|  | 391.6 | 0.258 | $90\left(V_{1}^{1}\right)$ | 395.6 | 0.263 | $90\left(V_{1}^{1}\right)$ | 403.9 | 0.281 | $90\left(V_{1}^{1}\right)$ |
|  | 339.2 | 0.299 | $75\left(V_{3}^{1}\right), 10\left(V_{2}^{1}\right)$ | 341.4 | 0.301 | $75\left(V_{3}^{1}\right), 10\left(V_{2}^{1}\right)$ | 346.4 | 0.300 | $76\left(V_{3}^{1}\right), 9\left(V_{2}^{1}\right)$ |

All electron transitions are of $\pi \rightarrow \pi^{*}$ type.
and $\mathrm{Cl}=980$ all the 35 occupied MO's and 15, respectively 28 unoccupied MO's were taken into account in Cl . For $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ configuration interaction does not reflect the value of $f$, while for $\mathrm{ACH}_{2}^{+}$ the taking into account of 980 monoexcited configurations leads to its considerable increase at the transition $S_{0} \rightarrow S_{1}$ and decrease at the transition $S_{0} \rightarrow S_{2}$. If 980 monoexcited configurations are taken into account, the electron transitions $S_{0} \rightarrow S_{2}$ and $S_{0} \rightarrow S_{3}$ for $\mathrm{ACH}_{2}^{+}(\mathrm{eq})$ fall into the region of the bands with maxima at $\lambda=401$ and 354 nm , while for partial taking into account of the monoexcited configurations $\mathrm{Cl}=240,525$ these transitions are shifted to the shortest wavelength and do not pass into the region of these bands.
