#### Abstract

The 1,3-dipolar cycloadditions of nitrones to $N$-(2,6-dialkylphenyl)maleimides give mainly antiadducts. The $Z / E$ isomerization of nitrones and the sterically preferred exo attack avoiding the repulsions between $N$-arylmaleimide and $N$-phenyl moiety of nitrone was proposed. The reaction of $N$-(2-ethyl-6-methylphenyl)maleimide with nitrone gave, due to hindered rotation, two or four types of diastereoisomers characterized by different spatial arrangement of alkyl groups vs. bridgehead hydrogen atoms.

Some compounds of dicarboximide type are reported to reveal effective systemic activity against Botrytis cinerea, Cochliobolus miyabeanus, and Pellicularia sasaci [1]. Within the scope of our ongoing research aimed at utilization of 1,3-dipolar cycloadditions to heterocycles we have recently found [2] that the reaction of N -(2-ethyl-6-methylphenyl)maleimide with nitrile oxide gave, due to hindered rotation, two diastereoisomers characterized by different spatial arrangement of alkyl groups vs. bridgehead hydrogen atoms [3]. Since that is a very rare phenomenon we have focused our attention to the cycloaddition of nitrones to N -(2,6-dialkylphenyl)maleimides.

1,3-Dipolar cycloaddition of C-(2,4-dichloroben-zoyl)-N-phenyl nitrone (IIa) and $N$-(2,6-dimethylphenyl)maleimide (la) in benzene at room temperature afforded the anti-isoxazolidine IIIa (Scheme 1, $\mathrm{H}-3, \mathrm{H}-3 \mathrm{a}$ anti relationship) in 88 \% yield. The NMR analysis of the crude mixture showed the presence of the second isomer IVa, but in the amount less than $10 \%$. This compound could not be isolated from the major product in pure form. Similarly, treatment of the corresponding $C$-benzoyInitrone IIb with la gave anti-isoxazolidine IIIb. On the other hand, it was found that $C, N$-diphenylnitrone (IIc) reacted with la in benzene at $80^{\circ} \mathrm{C}$ to give a mixture of anti IIIC and syn IVc cycloadducts. The crude residue was chromatographically separated, and each cycloadduct IIIc and $I V c$ could be obtained in pure form. The NMR analysis of the crude mixture gave the mass ratio 72 : 28 in favour of IIIc. There are two possible adducts of la and nitrones lla-llc, two diastereoisomers III and IV. The distinction between them was possi-

[^0]

ble by means of spectroscopic data. Stereochemical assignments of $\mathrm{H}-3, \mathrm{H}-3 \mathrm{a}$, and $\mathrm{H}-6 \mathrm{a}$ atoms were made to the condensed isoxazolidines on the basis of the $J_{3,3 \mathrm{a}}$ and $J_{3 \mathrm{a}, 6 \mathrm{a}}$ coupling constant. The ring junction between two rings was always cis, which was indicated by coupling constants and an examination of molecular models. Moreover, all up-to-date known 1,3-dipolar cycloadditions of nitrones to alkenes proceeded with cis stereospecificity [4]. For instance, in the compounds IIla the coupling constant for the cis ring junction protons $\mathrm{H}-6 \mathrm{a}$ and $\mathrm{H}-3 \mathrm{a} J_{3 \mathrm{a}, \mathrm{ba}}=8.4$ Hz and in IIIc $J_{3 \mathrm{a}, 6 \mathrm{a}}=7.2 \mathrm{~Hz}$; in $I V c J_{3 \mathrm{a}, 6 \mathrm{a}}=8.1 \mathrm{~Hz}$, which is indicative of nearly eclipsed dihedral angles between $\mathrm{H}-3 \mathrm{a}$ and $\mathrm{H}-6 \mathrm{a}$.

Proton NMR analysis of isoxazolidines IIIa-IIIc revealed that each diastereoisomer has a $\mathrm{H}-3, \mathrm{H}-$ 3a anti relationship. In IIla, for example, the signal for H -3a proton appears as a doublet at $\delta=4.71$ with a coupling constant of $J_{3 \mathrm{a}, 6 \mathrm{a}}=8.4 \mathrm{~Hz}$ from coupling solely to the $\mathrm{H}-6$ a proton. In the $\mathrm{H}-3, \mathrm{H}-3 \mathrm{a}$ antiadducts the protons $\mathrm{H}-3$ and $\mathrm{H}-3 \mathrm{a}$ fail to display coupling since $\phi=90^{\circ}$. This feature of NMR spectrum is uniquely diagnostic of the $\mathrm{H}-3, \mathrm{H}-3 \mathrm{a}$ anti relationship [5]. In IIIa and IIIc the 0-1 Hz coupling constant between bridgehead $\mathrm{H}-3 \mathrm{a}$ and isoxazolidine H -3 (in IIla $J_{3,3 \mathrm{a}}=0.0 \mathrm{~Hz}$, in IIIc $J_{3,3 \mathrm{a}}=1.2 \mathrm{~Hz}$ ) is consistent only with anti stereochemistry, since in a syn-isomer IV the two hydrogens would be nearly eclipsed and would give rise to a much larger coupling constants. Indeed, the isolated adduct IVc from the cycloaddition of $\mathrm{C}, \mathrm{N}$-diphenylnitrone showed $J_{3,3 \mathrm{a}}=8.1 \mathrm{~Hz}$, which is in the range expected for a H 3, H-3a syn relationship. Further support for this syn relationship is the signal for the $\mathrm{H}-3 \mathrm{a}$ proton appearing as a doublet of doublets.

The diastereomeric isoxazolidines III and IV were formed via different two-plane orientation complexes (Scheme 2). The anti-isoxazolidines III arise from the cycloaddition of $Z$-nitrone I/ through an endo transition state ( $N$-Ph and $N$-aryl groups are on the same sides), or from the $E$-nitrone in an exo mode ( $N-\mathrm{Ph}$ and $N$-aryl groups are on the opposite sides).
Conversely the syn-isoxazolidines $I V$ could be formed by the $Z$-nitrone reacting in the exo fashion or the $E$-nitrone in an endo mode [6, 7]. The ratio of diastereoisomers should reflect secondary orbital interactions and repulsive interactions caused by steric hindrance [4]. An examination of both transition states in these terms reveals that secondary orbital interactions are not significant and that repulsions between the phenyl and aryl groups on nitrogens are minimized in the exo transition state. There is strong evidence that nitrones derived from aromatic aldehydes possess a configuration in which the $C$-aryl and $C$-aroyl, respectively, and $N$-phenyl groups are in a trans relationship ( $Z$-configuration of nitrone) [8]. The isomeric E-nitrones (cis relationship between aryl groups) could not be isolated, but since it has been postulated that isomerization of $Z$-nitrones to the more reactive nitrones can precede cycloaddition [9], it is not possible to exclude that either $Z$ - or $E$-nitrones are involved in cycloadditions [10].
Therefore, the major isoxazolidines III should arise from cycloaddition of $Z$-nitrone /I through endo transition state (Scheme 2). Molecular models suggest that an attack via endo mode is at least sterically unlikely. For endo transition state severe steric interactions occur between the incoming N -arylmaleimide as a consequence of the hindered rotation and N -phenyl moiety of nitrone II. We propose that the aforementioned nitrones undergo $Z \rightarrow E$ isomerization, since both anti III and syn IV cycloadducts obtained in these cycloadditions using N -(2,6-dimethylphenyl)maleimide as the dipolarophile must arise from the exo transition state; the E-isomer of the nitrone Ila-IIc yields the anti-adduct III, while the $Z$-isomer of IIc yields the syn-adduct IVc. The proposed ZIE nitrone isomerization was involved by many authors to account for the diastereoselectivity of 1,3-dipolar cycloaddition of nitrones with alkenes [9-12].
1,3-Dipolar cycloaddition of nitrone Ila and N -(2-ethyl-6-methylphenyl)maleimide (Ib) in benzene at room temperature affords the isoxazolidines Va and Vla as a mixture of diastereoisomers, from which only the preponderant anti-isomer Va could be isolated in the pure state (see Experimental). The ratio of Va to Vla 80 : 20 was determined by integration of the $\mathrm{H}-3, \mathrm{H}-3 \mathrm{a}$, and $\mathrm{H}-6$ a signals in the ${ }^{1} \mathrm{H}$ NMR spectra.
Similarly, C-benzoylnitrone Ilb with lb gave only anti-isoxazolidines $V b$ and $V I b$ in the ratio of $50: 50$. The possible stereoisomers VIIa, VIIb as well as

VIIIa, VIIIb have not been detected in the crude reaction mixture by NMR spectroscopy. In contrast to the mentioned examples the cycloaddition of $\mathrm{C}, \mathrm{N}$ diphenylnitrone to lb gave the anti-isoxazolidines Vc + VIc together with syn-isoxazolidines VIIIc + VIIIc, the ratio 72 : 28 was determined by NMR spectroscopy. The crude residue after cycloaddition was chromatographed, but only the mixture of antiadducts Vc + VIc and of syn-adducts VIIc + VIIIc both indicating a 1:1 ratio of stereoisomers could be obtained.
As a consequence of the hindered rotation and unsymmetrical substitution of the $N$-phenyl ring of maleimide four diastereomeric transition states of 1,3 -cycloaddition can be envisioned. The attack of the dipole at the double bond can in principle be carried out from the syn side of the methyl group (derivatives anti-syn V and syn-anti VII; the first prefix anti or syn showed a relationship between H-3 and $\mathrm{H}-3 \mathrm{a}$ atoms and the second a relationship between $\mathrm{H}-3$ and methyl group bound directly to the benzene ring) or from the opposite side (derivatives anti-anti VI and syn-syn VIII). Consequently, the diastereomeric cycloadducts (atropisomers) differ in the spatial arrangement of their alkyl groups towards the bridgehead proton H-3a and H-6a. The attempted chromatographic separation of atropisomers was successful only in case of anti-syn Va; this isomer could be isolated in a pure state. The assignment of structure of Va was done based on comparison with derivatives $I X$ and $X[2]$ and mainly by the fact that the repulsion of an alkyl group located in proximity to bridgehead protons causes their deshielding, an effect which indeed is substantiated by the measured values (see Experimental). Thus, the triplets of methyl protons of the ethyl groups in anti-syn Va were found at $\delta=1.13$, whereas in anti-anti VIa at $\delta=0.85$. Singlets of methyl group protons bound directly to the benzene ring in Va were found at $\delta=$ 1.30, those of VIa at higher value, $\delta=2.06$. Similar differences are observed also in quartets of the methylene groups protons as well as in signals of ${ }^{13} \mathrm{C}$ NMR spectra.

## EXPERIMENTAL

Melting points are not corrected. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of deuterochloroform solutions were measured with Varian VXR 300 instrument, tetramethylsilane being the internal reference. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of the raw reaction mixture were recorded on a Tesla BS $487 \mathrm{C}(80 \mathrm{MHz})$ spectrometer.
The progress of the cycloaddition was monitored by thin-layer chromatography on silica gel, impregnated by a fluorescence indicator (254 nm). $N$-(2,6Dialkylphenyl)maleimides I were prepared by the
reaction of maleic anhydride with 2,6-dialkylanilines [13]. C-(2,4-Dichlorobenzoyl)- $N$-phenylnitrone and $C$ -benzoyl- $N$-phenylnitrone were prepared according to Ref. [14]. C,N-Diphenylnitrone was prepared from the benzaldehyde by treatment with $N$-phenylhydroxylamine [4].

## 2,5-Diaryl-3-aroyl-4,6-dioxo-2,3,3a,4,6,6a-hexa-hydropyrrolo[3,4-d]isoxazoles III-VI

C-Aroyl- N -phenyInitrone Ila or II b ( 10 mmol ) and the appropriate dipolarophile / $(10-50 \mathrm{mmol})$ in benzene ( $50 \mathrm{~cm}^{3}$ ) or chloroform ( $50 \mathrm{~cm}^{3}$ ) were stirred at room temperature for 12-24 h (TLC monitoring). In some cases the cycloadduct was precipitated from the reaction mixture. The solvent was evaporated under reduced pressure, the residue was purified on silica gel to give the product. Characteristic data for compounds are as follows:
2-Phenyl-3-(2,4-dichlorobenzoyl)-5-(2,6-dimethyl-phenyl)-4,6-dioxo-2,3,3a,4,6,6a-hexahydropyrrolo-[3,4-d]isoxazole (IIIa), yield $=88 \%$ (benzene) or 64 \% (chloroform), m. p. $=192-194^{\circ} \mathrm{C}$ (decomp.). For $\mathrm{C}_{26} \mathrm{H}_{20} \mathrm{Cl}_{2} \mathrm{~N}_{2} \mathrm{O}_{4}\left(M_{\mathrm{r}}=495.35\right) w_{\mathrm{i}}$ (calc.): $62.99 \%$ C, 4.07 \% H, 5.65 \% N; $w_{\text {i }}$ (found): 62.62 \% C, 4.08 $\% \mathrm{H}, 5.66 \% \mathrm{~N} .{ }^{1} \mathrm{H}$ NMR spectrum, $\delta: 7.01-7.41$ ( m , $11 \mathrm{H}, \mathrm{H}_{\text {arom }}$ ), 5.93 (s, $1 \mathrm{H}, \mathrm{H}-3$ ), 5.24 (d, $1 \mathrm{H}, \mathrm{H}-6 \mathrm{a}$, $J_{3 \mathrm{a}, 6 \mathrm{a}}=8.4 \mathrm{~Hz}$ ), 4.71 (d, 1H, H-3a), 2.06 (s, 3H, CH3 $)$, $1.27\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{CH}_{3}\right) .{ }^{13} \mathrm{C}$ NMR spectrum, $\delta: 196.10$ ( s , $\mathrm{C}=\mathrm{O}$ ), 173.41 (s, $\mathrm{C}=\mathrm{O}$ ), 172.17 ( $\mathrm{s}, \mathrm{C}=\mathrm{O}$ ), 146.73, 137.94, 136.46, 135.64, 134.84, 131.40, 130.56, 130.02, 129.69, 129.56, 129.48, 128.39, 127.58, 123.72, $114.63\left(\mathrm{C}_{\text {arom }}\right), 77.67$ (d, C-6a), 71.73 (d, C3), 50.19 (d, C-3a), $17.91\left(\mathrm{q}, \mathrm{CH}_{3}\right), 16.35\left(\mathrm{q}, \mathrm{CH}_{3}\right)$.

2-Phenyl-3-(benzoyl)-5-(2,6-dimethylphenyl)-4,6-dioxo-2,3,3a,4,6,6a-hexahydropyrrolo[3,4-d]isoxazole (IIIb), yield = $36 \%$ after column chromatography, eluent heptane-ethyl acetate mixture ( $\varphi_{\mathrm{r}}=2: 1$ ), m. p. $=186-187{ }^{\circ} \mathrm{C}$. # Synthesis of 2-Acylaminobenzimidazoles from Acyl Isothiocyanates and o-Phenylenediamine 

P. KUTSCHY, V. FICERI, and M. DZURILLA<br>Department of Organic Chemistry, Faculty of Natural Sciences, P. J. Šafárik University, SK-041 67 Košice

Received 4 December 1992

Acyl isothiocyanates react with o-phenylenediamine in anhydrous acetonitrile in the presence of dicyclohexylcarbodiimide as cyclodesulfurizing agent with the formation of acyl derivatives of 2-aminobenzimidazole. Intermediates of the reaction are corresponding N -(2-aminophenyl)- $\mathrm{N}^{\prime}$ acylthioureas readily formed at laboratory temperature, which cyclize to benzimidazole derivatives by the action of dicyclohexylcarbodiimide in boiling acetonitrile.

Amongst 2-aminobenzimidazole derivatives there are some compounds exhibiting an expressive biological activity. For instance, methyl $N$-(2-benzimidazolyl)carbamate is used as broad spectrum systemic fungicide [1] and some of its derivatives are known as anthelmintics [2]. These compounds can be prepared by the reaction of o-phenylenediamine derivatives with methyl $N$-cyanocarbamate [3]. In the year 1977 appeared a paper reporting on the preparation of 2 -alkylamino- and 2 -arylaminobenzimidazoles from $N$-(2-aminophenyl)- $N^{\prime}$-substituted thioureas by the action of dicyclohexylcarbodiimide as cyclodesulfurizing agent in boiling benzene [4]. This approach was later applied in the synthesis of pyrimidine analogues of benzimidazoles from 4,5-diaminopyrimidine derivatives and methoxycarbonyl isothiocyanate under reflux in acetonitrile in the presence of dicyclohexylcarbodiimide [5]. Starting from this knowledge and in continuation of our
previous research on acyl isothiocyanates we have studied the possibility of employment of different acyl isothiocyanates in the synthesis of 2-acylaminobenzimidazoles via the reaction with o-phenylenediamine and subsequent cyclodesulfurization by dicyclohexylcarbodiimide. We found that acyl isothiocyanates / readily react with o-phenylenediamine in dry acetonitrile at laboratory temperature with the formation of $N$-(2-aminophenyl)- $N^{*}$-acylthioureas (II). Thioureas Ild and Ilf were also prepared independently by the reaction of o-phenylenediamine with isothiocyanates Id and If in benzene. Addition of dicyclohexylcarbodiimide to a solution of independently prepared thiourea or to a solution of not isolated thiourea in acetonitrile at $50^{\circ} \mathrm{C}$ and following reflux of the reaction mixture for 2 h afforded 2-acylaminobenzimidazoles III (Scheme 1). The above-mentioned work [5] does not describe a detailed procedure. According to our experience for
