#### Abstract

Thermogravimetry (TG), differential thermal analysis (DTA), and other analytical methods have been applied to the investigation of the thermal behaviour and structure of the com-  $\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \cdot 5 \mathrm{H}_{2} \mathrm{O}(\mathrm{IV})\left(\mathrm{ac}=\mathrm{CH}_{3} \mathrm{COO}^{-}, \mathrm{Clac}=\mathrm{ClCH}_{2} \mathrm{COO}^{-}, \mathrm{Cl}_{2}\right.$ ac $=\mathrm{Cl}_{2} \mathrm{CHCOO}^{-}$, $\mathrm{Cl}_{3} \mathrm{ac}=\mathrm{Cl}_{3} \mathrm{CCOO}^{-}$, and caf $=$caffeine). Thermal decomposition of these compounds is a multistage process. The compositions of the complexes and the solid state intermediate and resultant products of thermolysis have been identified by means of elemental analysis and complexometric titration. The possible scheme of destruction of the complexes is suggested. Heating of the compounds first results in a release of water molecules. In complexes $I, I I$, and $I I I$ the loss of the volatile ligand (caf) occurs (on the TG curves) in one step (-2caf or - caf) and in complex $I V$ in two steps (- caf, - caf). The final product of the thermal decomposition was MgO . The thermal stability of the complexes increases in the sequence: $I, I V, I I, I I I$. Caffeine was coordinated to $\mathrm{Mg}(\mathrm{II})$ through the $\mathrm{N}(9)$ atom of its heterocyclic ring. IR data suggest a unidentate coordination of carboxylates to magnesium in complexes $I-I V$.

It is well-documented that heterocyclic compounds play a significant role in many biological systems, especially $N$-donor ligand systems being a component of several vitamins and drugs [1, 2]. It is not surprising, therefore, that many authors have investigated heterocyclic compounds and also examined them as ligands in coordination compounds of several central atoms [3-13]. In order to enhance understanding of drug-metal ion interactions, we have been studying the thermal properties of magnesium(II) complexes with caffeine, which is known as an important component of biological systems.

The revealment of the relationship between the structure and thermolysis of metal carboxylate complexes, the study of the influence of metal and ligand nature on the process of thermal decomposition are of a certain interest. This work is a continuation of previously reported studies [14-19] on the thermal and spectral properties of magnesium(II) complexes with pyridine and substituted pyridines. This paper describes the preparation of complexes formed by the acetate, mono-, di-, and trichloroacetates with caffeine, along with thermal analyses and IR spectral investigation of prepared complexes.

## EXPERIMENTAL

The complexes were prepared by treating caffeine ( 0.01 mol , complexes $I, I V$ and 0.005 mol , complexes II, III) with appropriate magnesium(II) acetate or halogenoacetate ( 0.005 mol ) in hot ethanol solution. The solution was left to stand at room temperature. The fine microcrystals that precipitated were filtered off, washed with cold ethanol and dried at room temperature.

The infrared spectra were obtained on Philips analytical PU9800 FTIR spectrometer by using Nujol mulls in the $\tilde{\nu}$ range $200-4000 \mathrm{~cm}^{-1}$. The thermal decomposition was carried out on Paulik-PaulikErdey Derivatograph (Type OD 102, MOM Budapest) in air atmosphere by using a platinum crucible with

a sample mass of 100 mg in the temperature range $20-1000^{\circ} \mathrm{C}$. The rate of temperature increase of $10^{\circ} \mathrm{C}$ $\min ^{-1}$ was chosen for all measurements.

Elemental analyses (C, H, N) were carried out by means of an Erba 1106 analyzer and the content of Mg was established by complexometric titration. The analytical data of the compounds $I-I V$ reported in Table 1 show a good agreement between the experimental and calculated data.

## RESULTS AND DISCUSSION

The thermal decomposition data of the compounds $I-I V$ are collected in Table 2. The complexes $I-I V$ are thermally relatively stable. Thermal decomposition of the compounds is the multi-stage process. The subsequent detachment of the ligands was observed. The final product was MgO .

The TG and DTA curves for $\mathrm{Mg}(\mathrm{ac})_{2}(\mathrm{caf})_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ are shown in Fig. 1. The TG curve for that complex indicates that it is stable at temperature up to $105^{\circ} \mathrm{C}$, when there begins the slow decomposition to MgO , as to the final product formed at $530^{\circ} \mathrm{C}$. The TG curve shows two bendings at $290^{\circ} \mathrm{C}$ and $475^{\circ} \mathrm{C}$. They correspond to the presence of two intermediate decomposition products: $\mathrm{Mg}(\mathrm{ac})_{2}(\mathrm{caf})_{2}$ and $\mathrm{Mg}(\mathrm{ac})_{2}$. The most probable thermal decomposition scheme is

$$
\begin{gathered}
\mathrm{Mg}(\mathrm{ac})_{2}(\mathrm{caf})_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O} \xrightarrow{105-290^{\circ} \mathrm{C}} \mathrm{Mg}(\mathrm{ac})_{2}(\mathrm{caf})_{2} \\
\mathrm{Mg}(\mathrm{ac})_{2}(\mathrm{caf})_{2} \xrightarrow{290-475^{\circ} \mathrm{C}} \mathrm{Mg}(\mathrm{ac})_{2} \\
\mathrm{Mg}(\mathrm{ac})_{2} \xrightarrow{475-530^{\circ} \mathrm{C}} \mathrm{MgO}
\end{gathered}
$$

The DTA curve for the complex (Fig. 1) presents two endothermic peaks at $160^{\circ} \mathrm{C}$ and $370^{\circ} \mathrm{C}$ corresponding to the loss of $3 \mathrm{H}_{2} \mathrm{O}$ and 2caf, respectively, and a broad exothermic maximum with the centre about $500^{\circ} \mathrm{C}$ corresponding to decomposition reactions of 2ac with simultaneous formation of MgO .

The TG and DTA curves for $\mathrm{Mg}(\mathrm{Clac})_{2}(\mathrm{caf})$. $2 \mathrm{H}_{2} \mathrm{O}$ are shown in Fig. 2. The TG curve for that complex indicates that it is stable at temperature up to $130^{\circ} \mathrm{C}$, when there begins the slow decomposition to MgO , as to the final product formed at $715^{\circ} \mathrm{C}$. The TG curve shows two bendings at $250^{\circ} \mathrm{C}$ and $500^{\circ} \mathrm{C}$. They correspond to the presence of two intermediate decomposition products: $\mathrm{Mg}(\mathrm{Clac})_{2}$ (caf) and $\mathrm{Mg}(\mathrm{Clac})_{2}$. The most probable thermal decomposition scheme is
$\mathrm{Mg}(\mathrm{Clac})_{2}(\mathrm{caf}) \cdot 2 \mathrm{H}_{2} \mathrm{O} \xrightarrow{130-250^{\circ} \mathrm{C}} \mathrm{Mg}(\mathrm{Clac})_{2}(\mathrm{caf})$

\end{gathered}
$$

The DTA curve for the complex (Fig. 2) presents two endothermic peaks at $180^{\circ} \mathrm{C}$ and $300^{\circ} \mathrm{C}$ corresponding to the loss of $2 \mathrm{H}_{2} \mathrm{O}$ and caf, respectively, and a broad exothermic maximum with the centre
about $650^{\circ} \mathrm{C}$ corresponding to decomposition reaction of 2Clac with simultaneous formation of MgO .

The TG and DTA curves for $\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}$ (caf). $\mathrm{H}_{2} \mathrm{O}$ are shown in Fig. 3. The TG curve for that complex indicates that it is stable at temperature up to $160^{\circ} \mathrm{C}$, when there begins the decomposition to MgO , as to the final product formed at $650^{\circ} \mathrm{C}$. The TG curve shows two bendings at $270^{\circ} \mathrm{C}$ and $440^{\circ} \mathrm{C}$. They correspond to the presence of two intermediate decomposi-

Fig. 3. TG and DTA curves of $\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}($ caf $) \cdot \mathrm{H}_{2} \mathrm{O}$.
tion products: $\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}$ (caf) and $\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}$. The most probable thermal decomposition scheme is

$$
\begin{aligned}
\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}(\mathrm{caf}) \cdot \mathrm{H}_{2} \mathrm{O} \xrightarrow{160-270^{\circ} \mathrm{C}} \mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}(\mathrm{caf}) \\
\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2}(\mathrm{caf}) \xrightarrow{270-440^{\circ} \mathrm{C}} \mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2} \\
\mathrm{Mg}\left(\mathrm{Cl}_{2} \mathrm{ac}\right)_{2} \xrightarrow{440-650^{\circ} \mathrm{C}} \mathrm{MgO}
\end{aligned}
$$

The DTA curve for the complex (Fig. 3) presents two endothermic peaks at $165^{\circ} \mathrm{C}$ and $330^{\circ} \mathrm{C}$ corresponding to the loss of $\mathrm{H}_{2} \mathrm{O}$ and caf, respectively, and an exothermic maximum at $540^{\circ} \mathrm{C}$ corresponding to decomposition reaction of $2 \mathrm{Cl}_{2}$ ac with simultaneous formation of MgO .

The TG and DTA curves for $\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}$ (caf $)_{2}$ $\cdot 5 \mathrm{H}_{2} \mathrm{O}$ are shown in Fig. 4. The TG curve for that complex indicates that it is stable at temperature up to $110^{\circ} \mathrm{C}$, when there begins the decomposition to MgO , as to the final product formed at $750^{\circ} \mathrm{C}$. The TG curve shows four bendings at $160^{\circ} \mathrm{C}, 225^{\circ} \mathrm{C}, 385^{\circ} \mathrm{C}$, and $550^{\circ} \mathrm{C}$. They correspond to the presence of four intermediate decomposition products: $\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}, \mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2}$, $\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}$ (caf), and $\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}$. The most probable thermal decomposition scheme is

$$
\begin{aligned}
& \xrightarrow{\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \cdot 5 \mathrm{H}_{2} \mathrm{O} \xrightarrow{110-160^{\circ} \mathrm{C}}} \begin{array}{l}
110-160^{\circ} \mathrm{C} \\
\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O} \\
\left.\mathrm{Mg}^{\prime} \mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O} \xrightarrow{160-225^{\circ} \mathrm{C}} \\
\xrightarrow{160-225^{\circ} \mathrm{C}} \mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2}
\end{array}
\end{aligned}
$$

$$
\begin{gathered}
\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf})_{2} \xrightarrow{225-385^{\circ} \mathrm{C}} \mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf}) \\
\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2}(\mathrm{caf}) \xrightarrow{385-550^{\circ} \mathrm{C}} \mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2} \\
\mathrm{Mg}\left(\mathrm{Cl}_{3} \mathrm{ac}\right)_{2} \xrightarrow{550-750^{\circ} \mathrm{C}} \mathrm{MgO}
\end{gathered}
$$

The DTA curve for the complex (Fig. 4) presents two endothermic peaks at $120^{\circ} \mathrm{C}$ and $175^{\circ} \mathrm{C}$ corresponding to the loss of $2 \mathrm{H}_{2} \mathrm{O}$ and $3 \mathrm{H}_{2} \mathrm{O}$, respectively, and an exothermic maximum with the centre about $250^{\circ} \mathrm{C}$ corresponding to decomposition reaction of caf. Further endothermic and exothermic peaks occur at $410^{\circ} \mathrm{C}$ and $700^{\circ} \mathrm{C}$ corresponding to the loss of remaining caf and $2 \mathrm{Cl}_{3} \mathrm{ac}$, respectively, with simultaneous formation of MgO .

According to the anion ligands, the thermal stability of the complexes is increased as follows: $I(\mathrm{ac})$, $I V\left(\mathrm{Cl}_{3} \mathrm{ac}\right), I I(\mathrm{Clac}), I I I\left(\mathrm{Cl}_{2} \mathrm{ac}\right)$. Heating of the compounds first results in a release of water molecules in one step in complexes $I-I I I$ and in two steps in complex $I V$. Caffeine was eliminated in complexes $I-I I I$ in one step and in complex $I V$ in two steps (- caf,
caf). The results of thermal decomposition of the complexes were compared with literature results of metal(II) complexes with carboxylates and halogenocarboxylates [20-23]. The stoichiometry of thermal decomposition can also be influenced by the changes of experimental conditions [24-26].

The modes of the coordinated ligands in the complexes have been investigated by means of infrared absorption spectra. The most important infrared frequencies attributed to the vibrations of the complexes $I-I V$ are reported in Table 3. The absorption bands

| $\nu(\mathrm{OH})$ |  | 3335 | 3239, 3366 | 3308 | 3380 |
| $\delta(\mathrm{HOH})$ |  | 1655 | 1643 | 1637 | 1651 |
| $\rho\left(\mathrm{H}_{2} \mathrm{O}\right)$ |  | 744, 758, 760 | 747, 760, 783 | 704, 769, 823 | 742, 760, 804 |
|  |  | 788, 800, 925 | 864, 951 | 854, 891, 943 | 833, 841, 941 |
| $\nu(\mathrm{Mg}-\mathrm{O})$ |  | 258, 370, 391 | 254, 277, 308 | 313, 390 | 320, 393 |

as $=$ asymmetric, $\mathrm{s}=$ symmetric.
$\nu(\mathrm{OH})$ and $\delta(\mathrm{HOH})$ which occur in the $\tilde{\nu}$ range $3239-$ $3380 \mathrm{~cm}^{-1}$ and $1637-1655 \mathrm{~cm}^{-1}$, respectively, confirm the presence of water of crystallization. The absorption bands which occur in the $\tilde{\nu}$ range $600-1000$ $\mathrm{cm}^{-1}$ (rocking and wagging stretching) and 258-393 $\mathrm{cm}^{-1} \nu(\mathrm{Mg}-\mathrm{O})$ confirm the presence of water as coordinated in the complexes [27]. The presence of water as water of crystallization and as coordinated water in the compounds is further supported by the thermal decomposition data. Carboxylate ions can coordinate to metal ions in a number of ways such as uniden-
tate, bidentate (chelating) or bridging and there is an evidence of that fact in the IR spectrum. The analysis of $\mathrm{COO}^{-}$group bands frequencies allowed on determination of parameter $\Delta_{\mathrm{COO}}=\tilde{\nu}\left(\nu_{\mathrm{as}}\left(\mathrm{COO}^{-}\right)\right)$ - $\tilde{\nu}\left(\nu_{\mathrm{s}}\left(\mathrm{COO}^{-}\right)\right)$. The magnitude of $\Delta_{\mathrm{COO}}$ has been used by Nakamoto [28] as a criterion of the way of carboxylate binding with metal ions. Calculated from the examined spectra values of $\Delta_{\text {Coo }}$ are in the $\tilde{\nu}$ range $235-303 \mathrm{~cm}^{-1}$. These values and three bands (COO deformation) at $720-920 \mathrm{~cm}^{-1}$ of complexes $I-I V$ are in good accord with the literature data for
unidentately bonded acetates structures [29]. The absorption bands which occur in the $\tilde{\nu}$ range $206-242$ $\mathrm{cm}^{-1}(\nu(\mathrm{Mg}-\mathrm{N}))$ confirm the coordination of caffeine to Mg ion through the $\mathrm{N}(9)$ atom of its heterocyclic ring [30]. The crystal structure of metal(II) complexes with caffeine also proved that the caffeine coordinates to metal ions through the $\mathrm{N}(9)$ atom of its heterocyclic ring [31].

Without X-ray analysis, no definite structure can be described for the different components. However, the spectroscopic and analytical data available enable to predict the structures which are supported also by the thermal decomposition studies.
